\boldsymbol{n}

O(m)

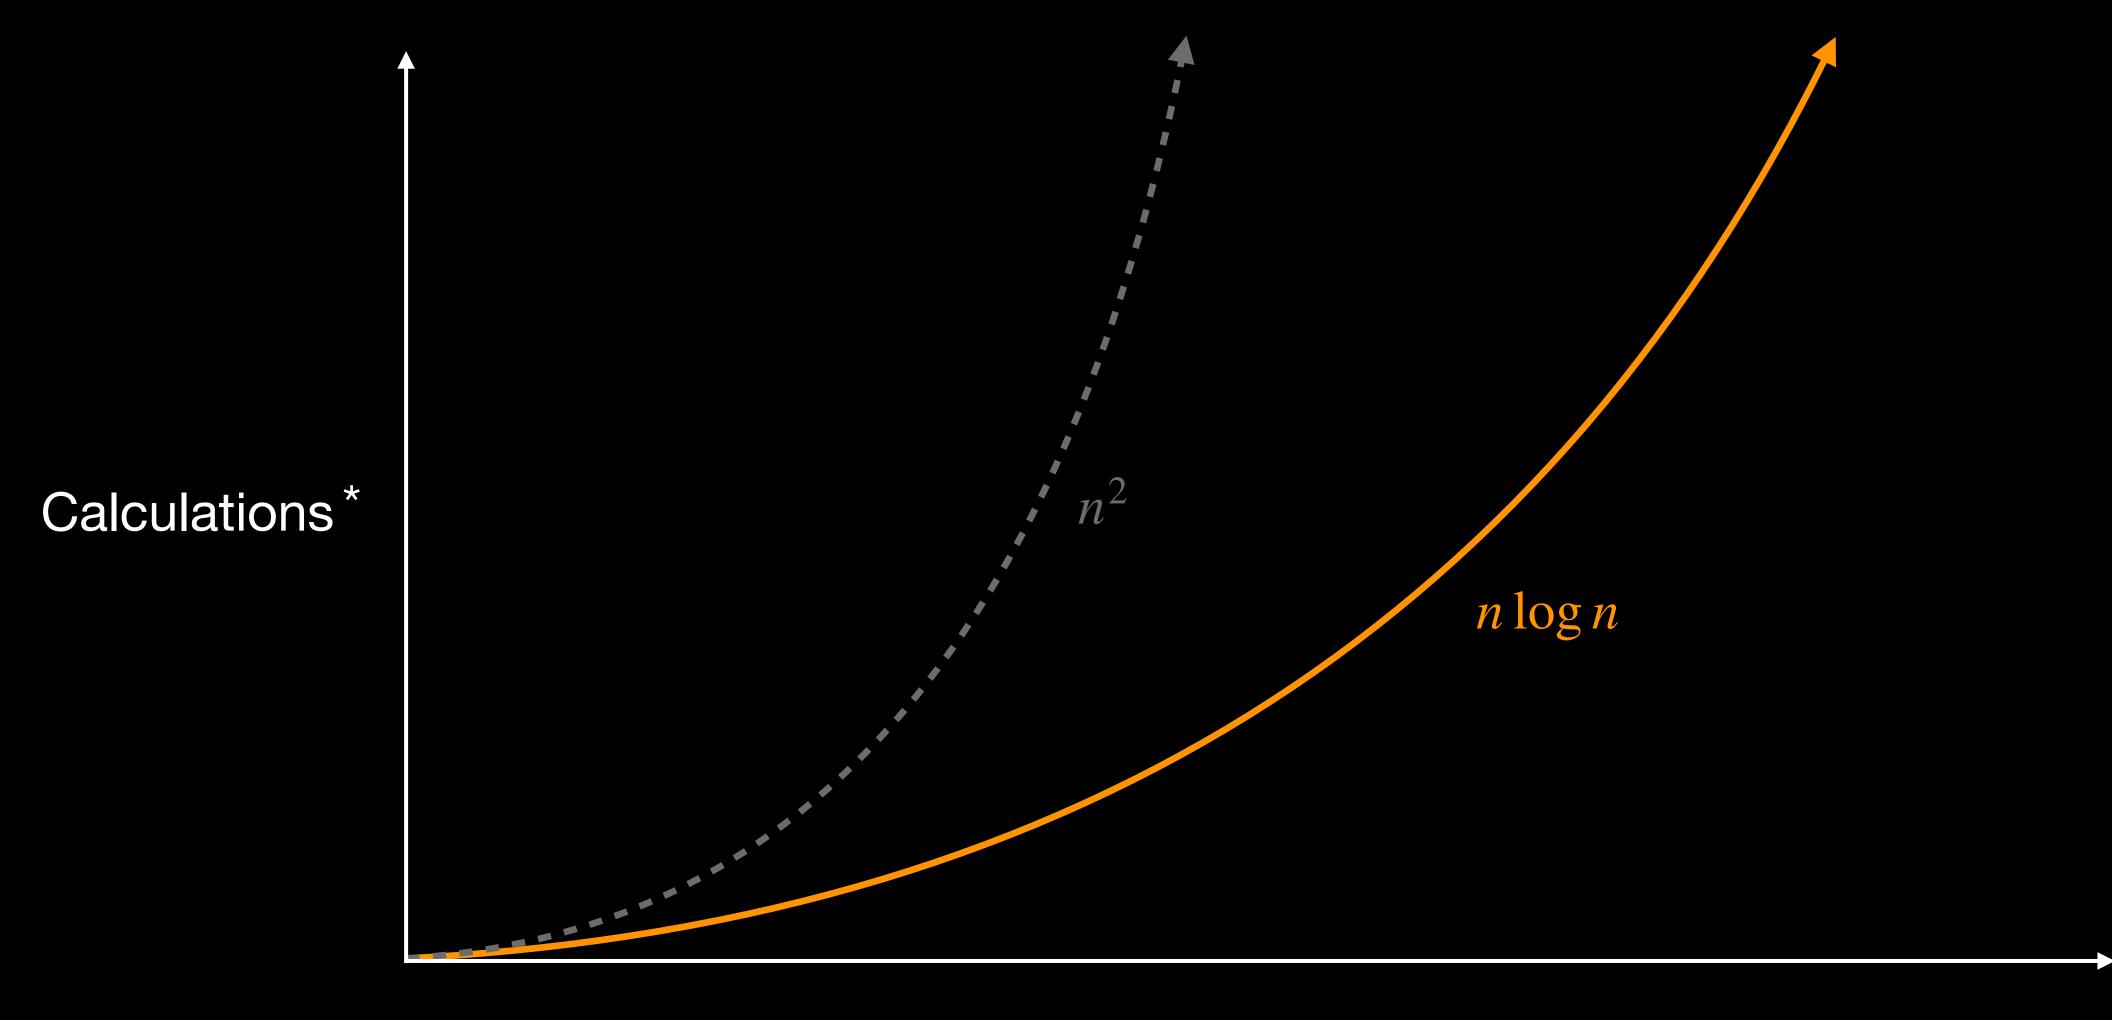

$\log_2(n)$

$\log_2(n)$

 $O(n \log n)$

How efficient is Merge Sort?

- Let our array contain *n* elements. Divide the full array into equal subarrays, each with 1 element.
- Each merge operation takes O(m), where each subarray has m elements.
- Each time we merge two subarrays, the resulting merged array is double the size of either subarray.
- We can double the size of any subarray at most $\log_2(n)$ before the subarray is of size n.
- So, we perform $log_2(n)$ merges, which could each take up to 2n operations.
- The overall running time is $O(n \log n)$.

Elements of Array (n)
